

Results: Citation Network

RQ4: Citation Geometry I

Resolving each record's references against the corpus yields an intra-corpus citation graph (built and analyzed with NetworkX [agberg2008exploring]) of 46 nodes and 48 edges across 10 connected components, with a graph density of 2.32% and a mean in-degree of 1.0. Of 96 total outgoing references, 50.0% resolve to another record inside the corpus. This resolution rate describes how self-contained the retrieved slice is; it is not an estimate of the underlying citation density of any individual work.

The citation network has 15 communities (detected by modularity optimization), a maximum in-degree of 6 (the most-cited paper within the corpus), and a maximum out-degree of 4 (the paper that cites the most other corpus members).

Centrality Analysis I

Centrality scores (PageRank [page1999pagerank] and HITS) and modularity-based community detection [clauset2004finding] are rounded and ranked with a stable tiebreaker so the reported hub and authority rankings are byte-reproducible across runs despite the floating-point non-associativity of the underlying iterative solvers.

Table 4. Top 5 papers by PageRank.

Rank	DOI	PageRank
1	10.5555/exoplanet_atmospheres.0000	0.100386
2	10.5555/exoplanet_atmospheres.0005	0.094693
3	10.5555/exoplanet_atmospheres.0008	0.089991
4	10.5555/exoplanet_atmospheres.0010	0.080374
5	10.5555/exoplanet_atmospheres.0015	0.044154

Centrality Analysis II

Table 5. Top 5 authority papers (HITS).

Rank DOI		Authority
1	10.5555/exoplanet atmospheres.0010	0.328136
2	10.5555/exoplanet atmospheres.0016	0.117442
3	10.5555/exoplanet atmospheres.0047	0.097992
4	10.5555/exoplanet atmospheres.0009	0.080540
5	10.5555/exoplanet atmospheres.0015	0.076253

Centrality Analysis III

Table 6. Top 5 hub papers (HITS).

Rank DOI		Hub
1	10.5555/exoplanet atmospheres.0057	0.126454
2	10.5555/exoplanet atmospheres.0018	0.121085
3	10.5555/exoplanet atmospheres.0078	0.115800
4	10.5555/exoplanet atmospheres.0056	0.111057
5	10.5555/exoplanet atmospheres.0015	0.089171

Centrality Analysis IV

The highest-ranked paper by PageRank (DOI 10.5555/exoplanet atmospheres.0000) is a central node in the retained citation graph. Its score indicates relative centrality within this graph, not scientific importance or causal influence. Hub papers cite many corpus members and may connect threads of the retrieved literature, but their role should be checked against their source type and content.

Centrality Analysis V

Citation Network (46 nodes, 48 edges)

Figure 1: Citation network for Exoplanet Atmospheres. Nodes represent papers; directed edges represent citation links. Node colours indicate community membership (15 communities detected by modularity optimization). Layout uses a spring-based algorithm with a fixed seed for reproducibility.

Centrality Analysis VI

Centrality Analysis VII

Figure 2: Degree distribution for the Exoplanet Atmospheres citation network. The histogram shows the frequency of each in-degree value on a log-linear scale, revealing the heavy-tailed structure characteristic of citation networks.

The heavy-tailed degree distribution is characteristic of citation networks: a small number of highly-cited papers anchor the structure, while the long tail of low-degree nodes represents newer or peripheral works. The low graph density (2.32%) reflects the sparsity of intra-corpus citation links. Many papers may cite works outside the retrieved slice, especially under a capped retrieval design.

Advanced Network Metrics I

Beyond PageRank and HITS, the network analysis computes betweenness centrality (which papers bridge different communities), closeness centrality (which papers are near all others), degree assortativity (do highly-cited papers cite other highly-cited papers?), and average clustering coefficient (how tightly knit are local neighborhoods).

The degree assortativity coefficient is -0.0325 , and the average clustering coefficient is 0.0601 . A negative assortativity indicates that highly-cited papers tend to cite less-cited papers (disassortative mixing), which is typical of citation networks where review papers (high in-degree) cite many primary studies (low in-degree).

Table 7. Top 5 papers by betweenness centrality.

Rank	DOI	Betweenness
1	10.5555/exoplanet_atmospheres.0010	0.021717
2	10.5555/exoplanet_atmospheres.0008	0.016667
3	10.5555/exoplanet_atmospheres.0015	0.012879
4	10.5555/exoplanet_atmospheres.0005	0.010606

Advanced Network Metrics II

5 10.5555/exoplanet atmospheres.0017 0.005051

Advanced Network Metrics III

Papers with high betweenness centrality occupy shortest paths between communities in the retained graph. Removing one may alter connectivity, but that graph operation does not by itself establish that the paper is a review or methodological bridge in the scientific field. Source-type and content review are required for that interpretation.
